Mineral Analysis

3. Thermal analyses.

- Differential thermal analysis (DTA).
- Differential scanning calorimetry (DSC).
- Thermogravimetric analysis (TGA).

Thermal Analysis

5. Thermal analyses

It is a method where the **properties of minerals** are studied as they **change with temperature**. Several methods are commonly used – these are distinguished from one another by the property which is measured:

1. **Differential thermal analysis (DTA):** temperature difference between (sample) and (muffle/standard) temperature or time.
2. **Thermogravimetric analysis (TGA):** mass change versus muffle temperature or time.
3. **Differential scanning calorimetry (DSC):** heat flow changes between (sample and standard) versus muffle temperature or time.
4. **Dielectric thermal analysis (DEA):** dielectric permittivity and loss factor.
5. **Dilatometry (DIL):** volume changes with temperature change.
6. **Dynamic mechanical analysis (DMA or DMTA):** measures storage modulus (stiffness) and loss modulus (damping) versus temperature, time and frequency.
7. **Evolved gas analysis (EGA):** analysis of gases evolved during heating of a material, usually decomposition products.
8. **Laser flash analysis (LFA):** thermal diffusivity and thermal conductivity.
9. **Thermomechanical analysis (TMA):** dimensional changes versus temperature or time.
10. **Thermo-optical analysis (TOA):** optical properties.

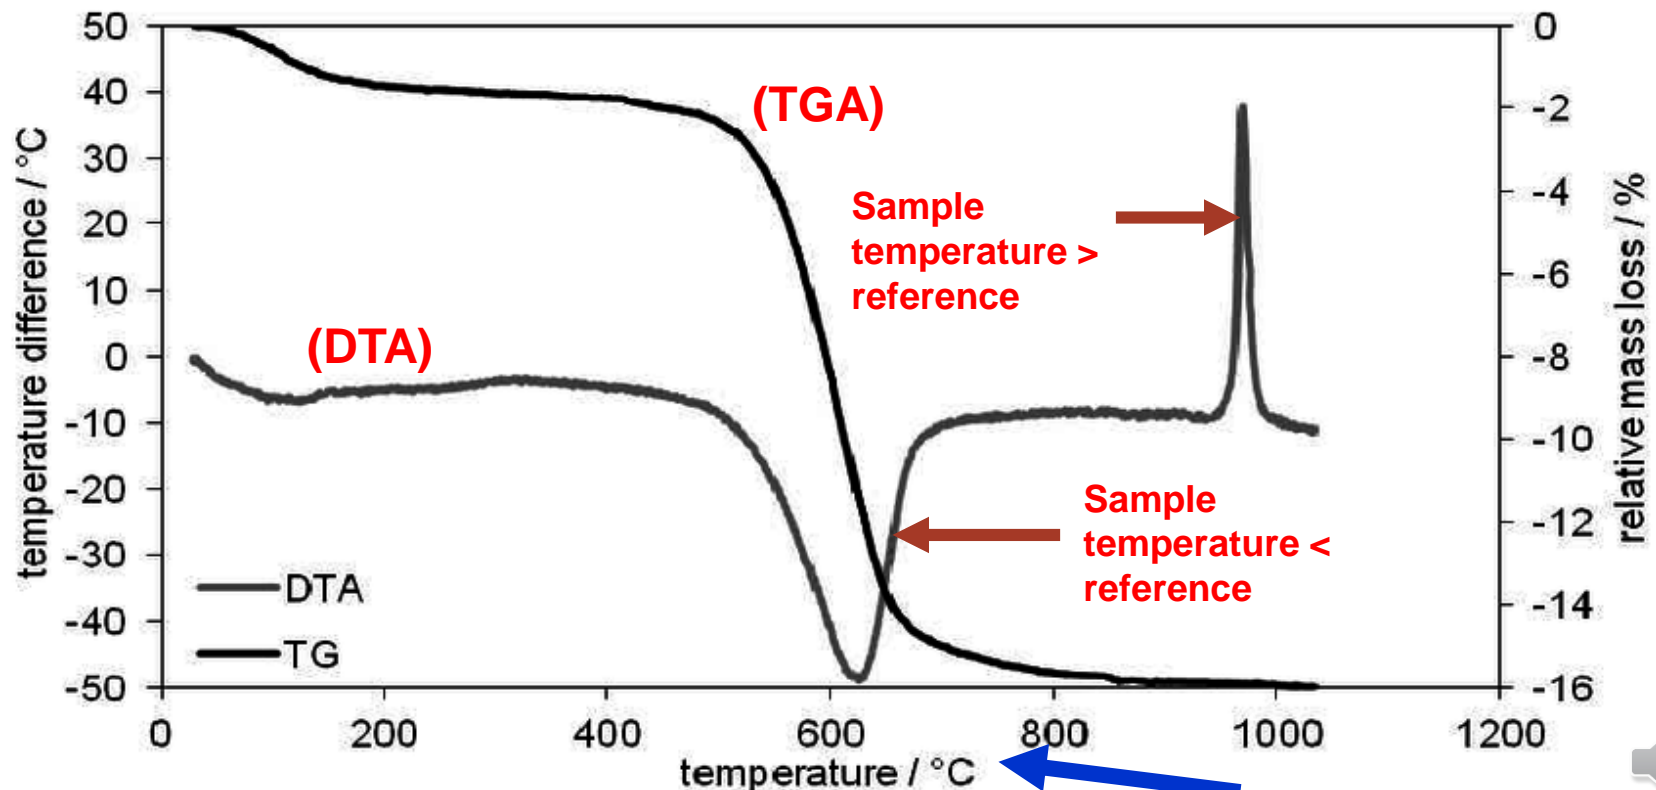

Common Thermal Analysis Methods and the Properties Measured

Method	Abbreviation	Property Measured
Differential thermal analysis	DTA	Temperature difference
Differential scanning calorimetry	DSC	Enthalpy
Thermogravimetric analysis	TGA	Mass
Dynamic mechanical analysis	DMA	Deformation
Dielectric thermal analysis	DEA	Deformation
Evolved gas analysis	EGA	Gaseous decomposition
Thermo-optical analysis	TOA	Optical properties

- Differential thermal analysis (DTA)

DTA is a technique for **identifying minerals and phases** by observing the thermal behavior of **a sample as it is heated**. The technique is based on the fact that as a mineral/rock sample is heated, **it undergoes reactions and phase changes that involve absorption or emission of heat within the sample**. DTA measures **the temperature necessary to establish a nearly zero-temperature-difference between the sample and the inert reference**

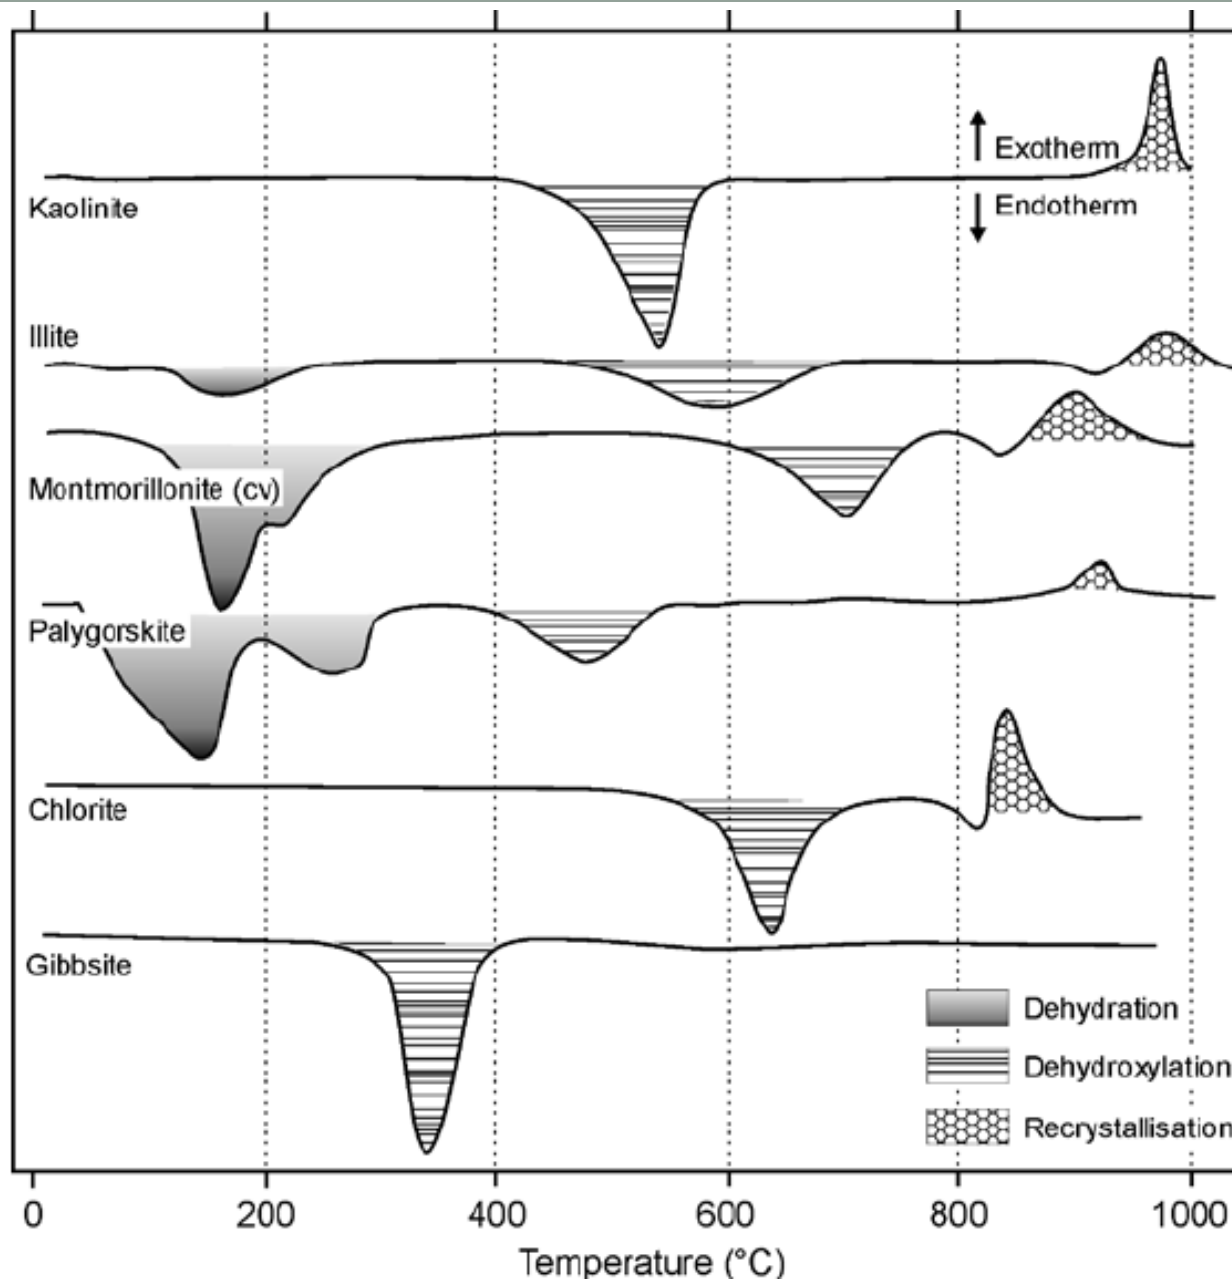

(Muffle/Reference sample temperature)

In **DTA** the temperature of the sample is measured relative to **an inert material**, i.e., **reference/standard (not suffering any phase change during heating)**. One thermocouple is imbedded in the sample (to measure the sample temperature during heating) and another in the inert material (to represent the inert/muffle temperature), then connected so that any **differential temperatures (temperature difference between both)** generated during heating (**muffle temperature**) are graphically recorded as a series of peaks.

Changes in the sample are either exothermic or endothermic. Thus, a **DTA curve** provides data on **the transformations that have occurred in the sample, such as decomposition, crystallization, melting and sublimation at a definite temperature**. The amount of heat (recorded by DCS) involved and temperature (recorded by DTA) at which these changes take place are characteristic for each mineral.

DTA of clay minerals

Explain the principle or theory of DTA.

- Differential scanning calorimetry (DSC)**

DSC measures the energy necessary to establish a nearly zero temperature difference between the sample and the inert reference as the two specimens are subjected to the same temperature at a controlled rate.

DSC provides quantitative and qualitative information about physical and chemical changes that involve endothermic or exothermic processes or change in heat capacity.

The area under the peak is directly proportional to the amount of heat energy absorbed or released by the sample.

DTA

DSC

- similar concept as DTA (compare sample & reference)
- measure "heat flow" required to keep both specimens same temperature

The basic principle underlying this technique is that when the sample undergoes a physical transformation such as phase transitions, **more-heat (energy)** or **less-heat (energy)** will need to flow **to/from** the sample than the reference to maintain both at the same temperature. Whether less or more **energy** must flow **to/from** the sample depends on whether the process is **endothermic** or **exothermic**.

For example, as a **solid sample** melts to a **liquid**, **it will require more energy (heat) flowing to the sample** to increase its temperature at the same rate as the reference. This is due to the **absorption of heat** by the sample as it undergoes the **endothermic phase** transition from solid to liquid (Ice cube is an example).

Likewise, as the sample undergoes **exothermic processes (such as crystallization)** **less heat is required to flow from the sample.** By observing the difference in heat flow between the sample and reference, **differential scanning calorimeters (DSC)** are able to measure **the amount of energy/heat flow absorbed or released during such transitions.**

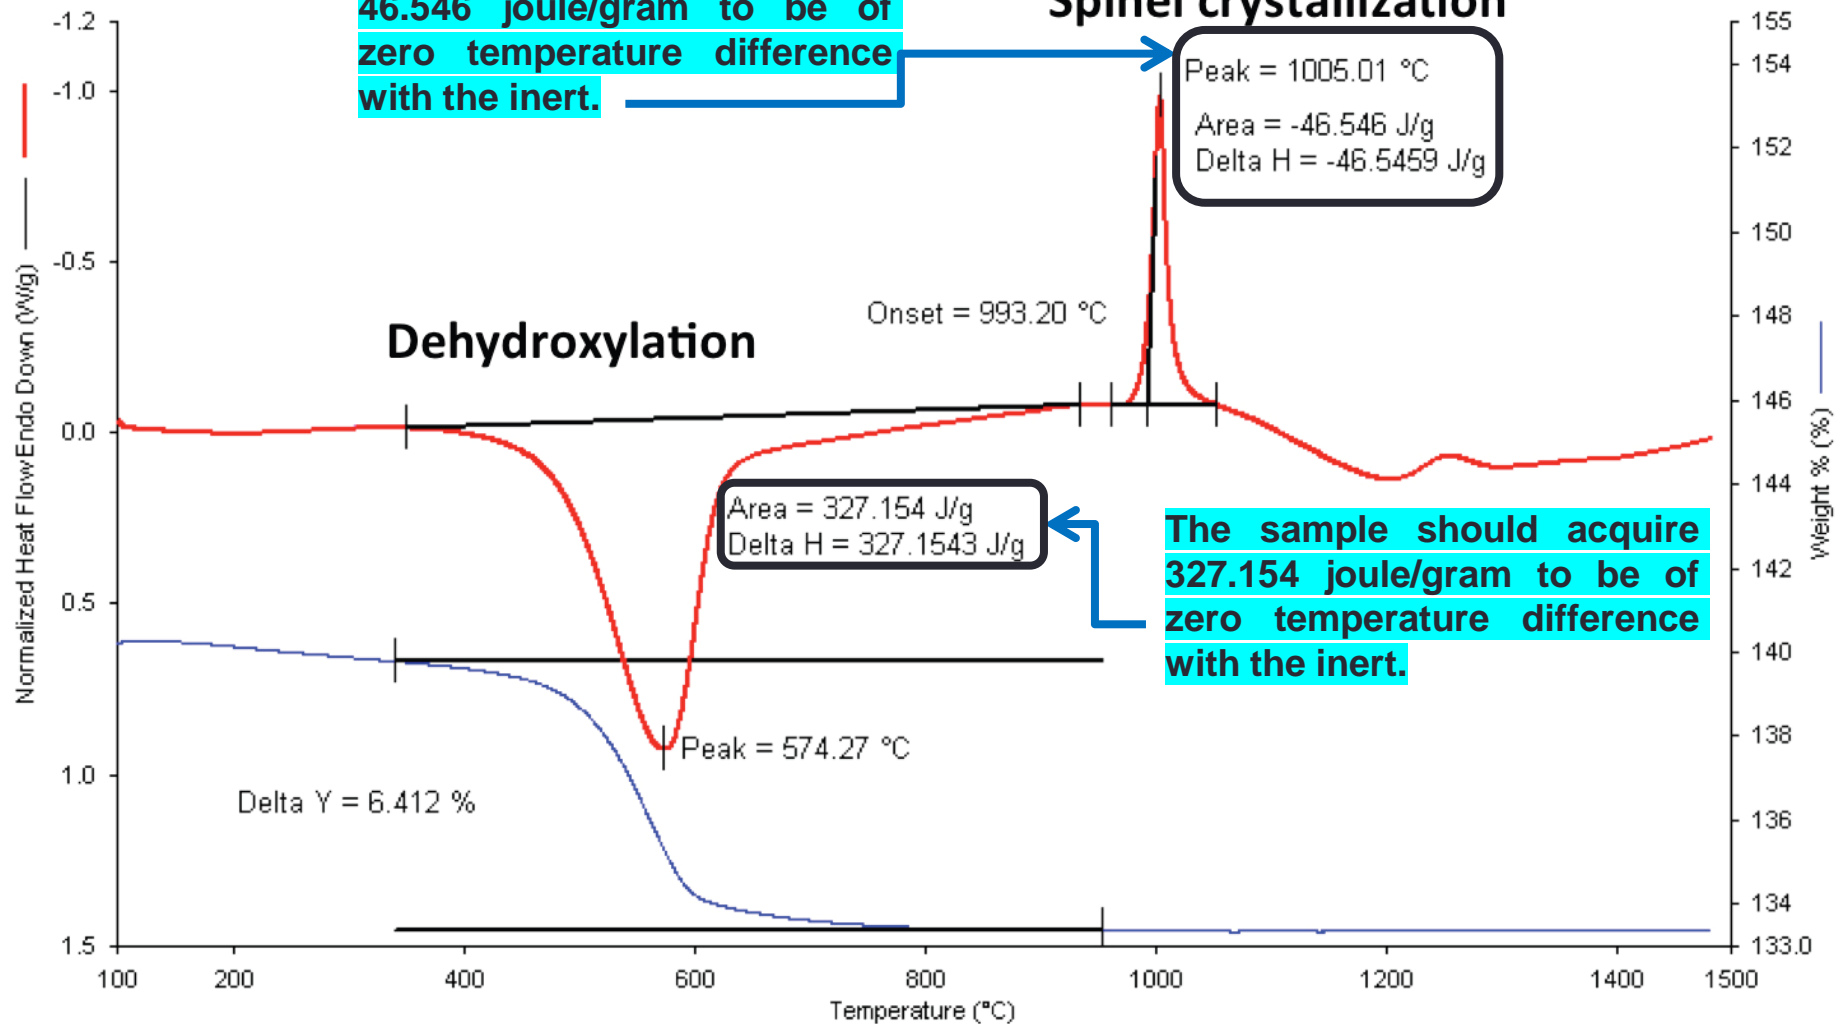

DSC of the ice, showing the ranges of melting and boiling values.

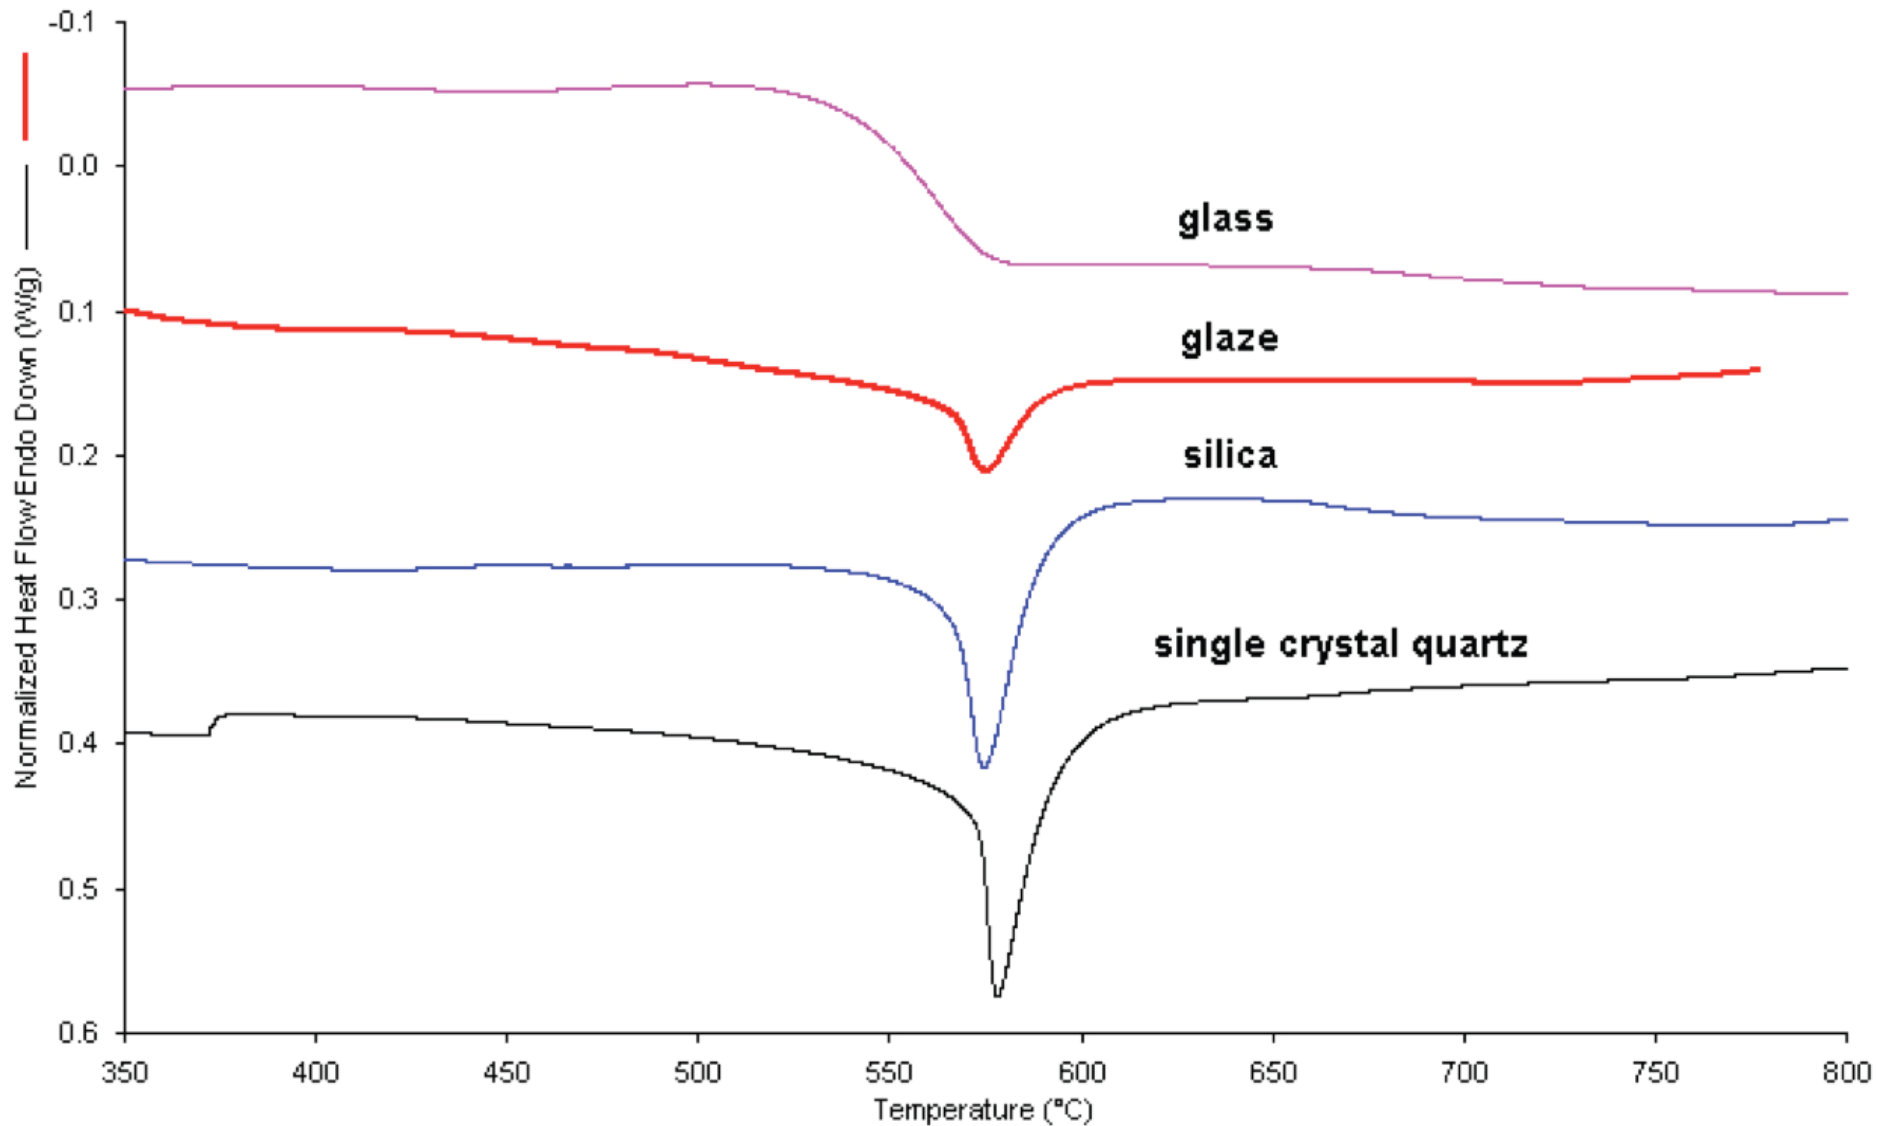

The sample should lose 46.546 joule/gram to be of zero temperature difference with the inert.

Spinel crystallization

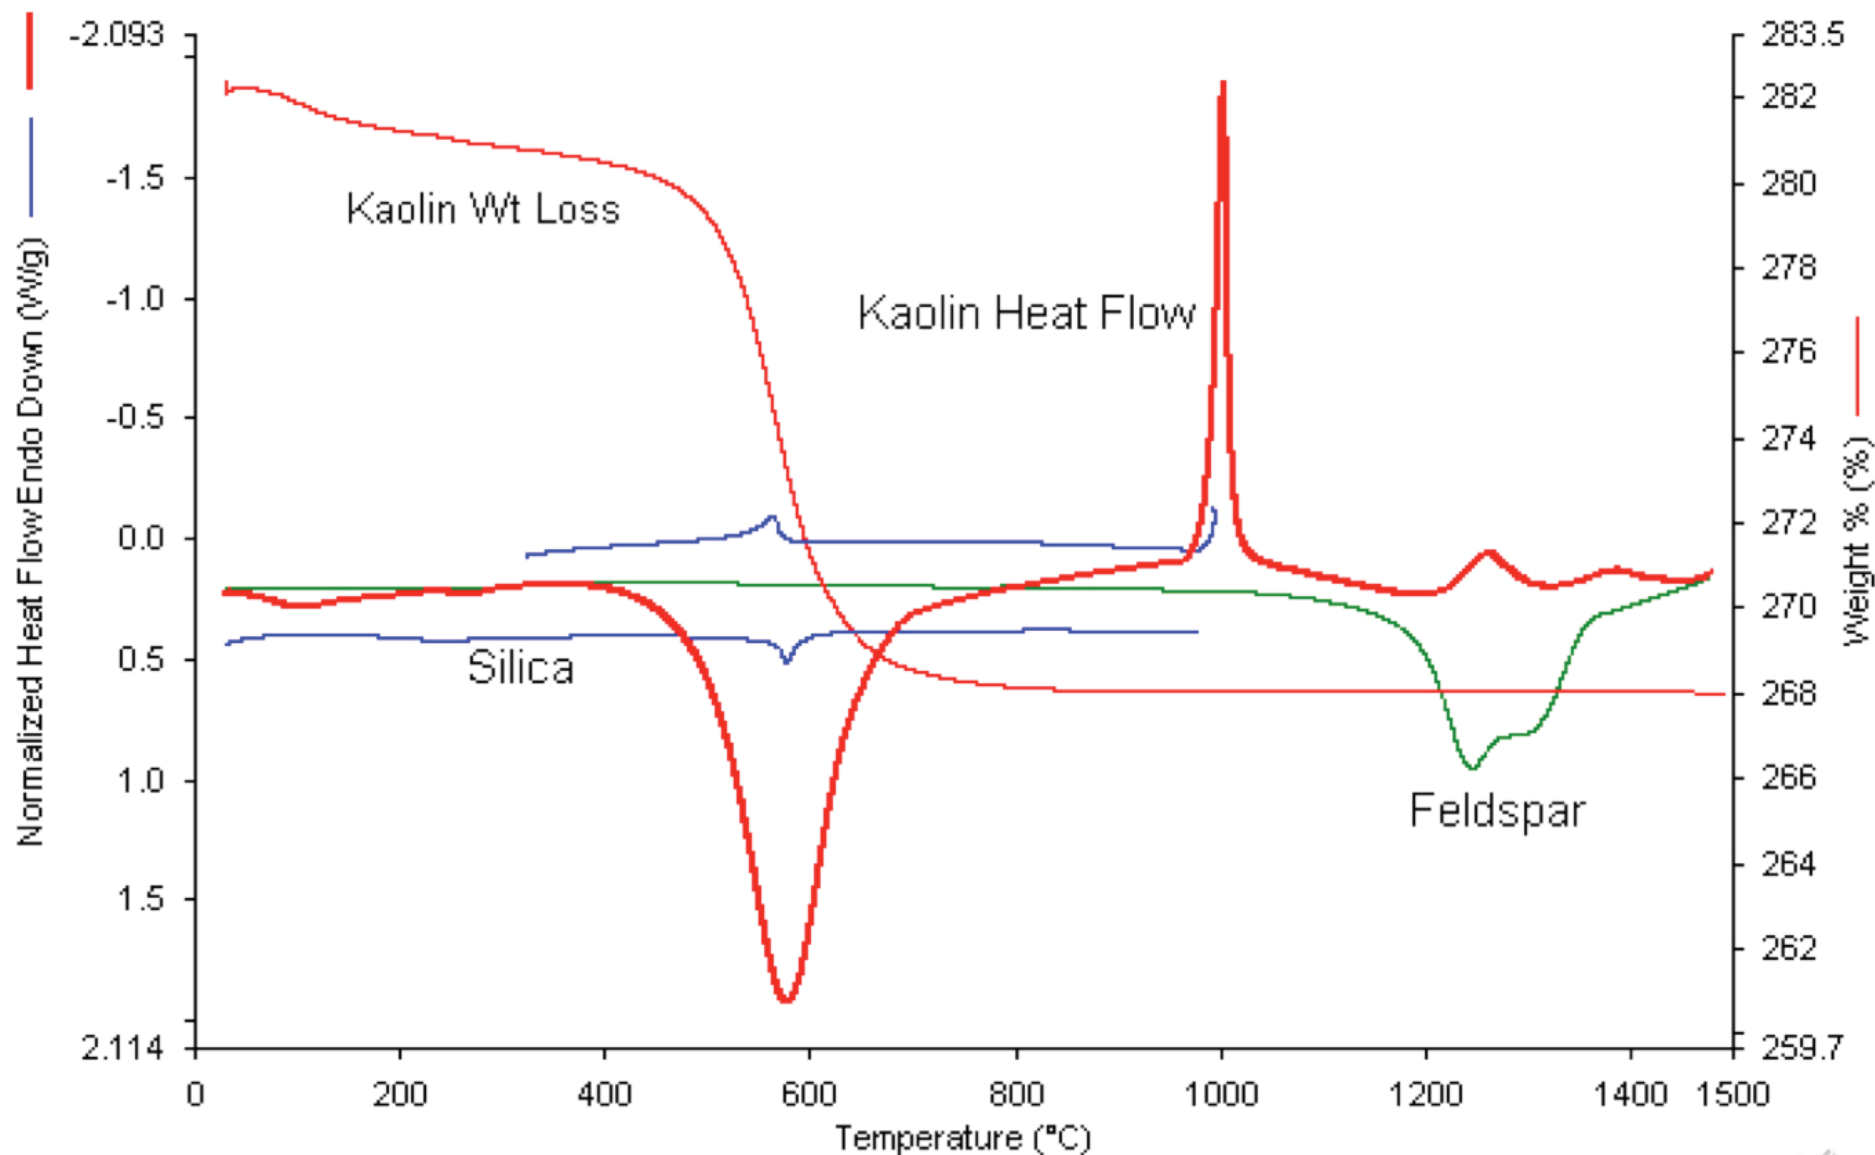

DSC and TGA of kaolinite.

Thermal curves of SiO₂ in window glass, unfired ceramic glaze, commercial silica and single quartz crystal.

Three main components of porcelain clay run individually (look carefully for the silica).

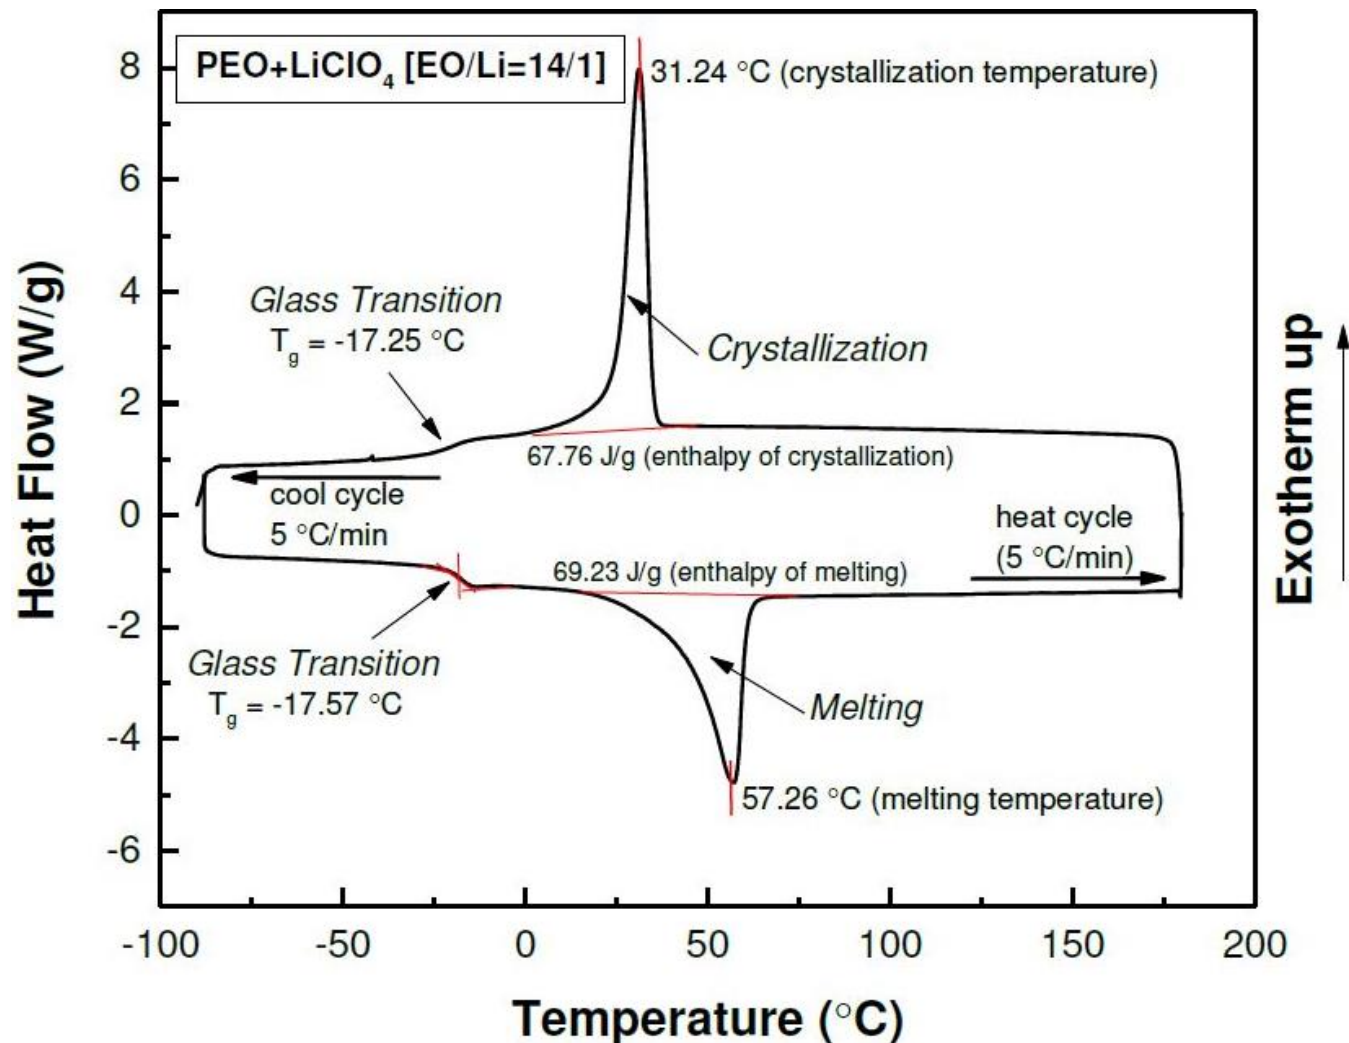

The amount of energy difference could be changed with time for the same material.

The basic principle underlying this technique is that when the sample undergoes a physical transformation such as phase transitions, more-heat (energy) or less-heat (energy) will need to flow to/from the sample than the reference to maintain both at the same temperature. Whether less or more energy must flow to/from the sample depends on whether the process is endothermic or exothermic.

• Thermogravimetric analysis or thermal gravimetric analysis (TGA)

TGA is a method of thermal analysis in which the **mass of a sample is measured as the temperature changes over time (no internal reference)**. This measurement provides information about physical phenomena, such as **phase transitions**, absorption and desorption; as well as chemical phenomena including chemi-sorptions, thermal decomposition, and solid-gas reactions (e.g., oxidation or reduction).

- as function of temperature
- as function of time (at constant temperature)

TGA thermogram of polymer-based composite material. The onsets of decomposition and residual mass are highlighted.

TGA VS DTA VS DSC

TGA is Thermal Gravimetric Analysis

The change of the mass of a sample with the change of the temperature is observed and analyzed

Used to analyze inorganic materials, metals, polymers, plastics, ceramics, glasses and composite materials

Sample can be used as a solid substance

DTA is Differential Thermal Analysis

The temperature difference developed between a sample and a reference compound is measured at identical heat treatments

Used to analyze thermal properties of minerals, for the characterization of polymers, and biological materials

Sample can be used as a solid substance

DSC is Differential Scanning Calorimetry

The heat flow is measured against the temperature change at a particular time

Used to analyze proteins, antibodies, etc.

Sample is always a liquid

NO	Technique Name	Abbreviation	Instrument Apply	Parameter Measure	Graph
1	Thermogravimetry	TG	Thermobalance	Mass	mass vs temp
2	Derivative Thermogravimetry	DTG	Thermobalance	dm/dt	dm/dt vs temp
3	Diff. Thermal Analysis	DTA	DTA Appts	ΔT	ΔT vs temp
4	Diff. Scanning Calorimetry	DSC	Calorimeter	dH.dt	dH/dt vs temp
5	Thermometric Titrimetry	Calorimeter	Temp.	Temp vs titrant volume
6	Dynamic Reflectance Spectroscopy	DRS	Spectrophotometer	Reflectance	%refle.and temp.

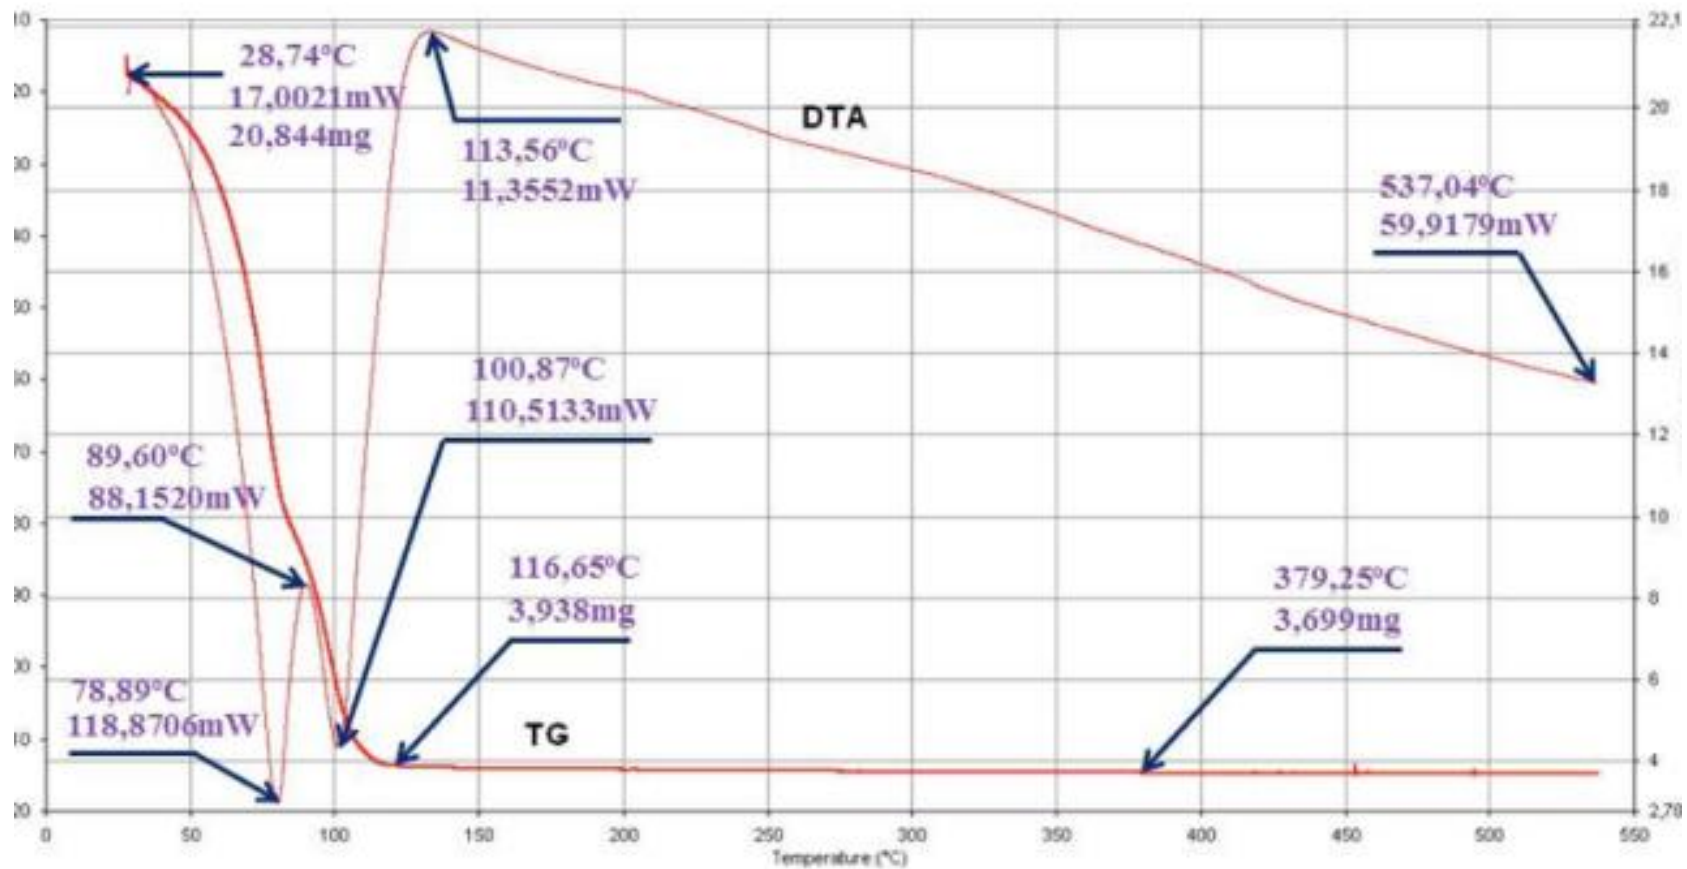

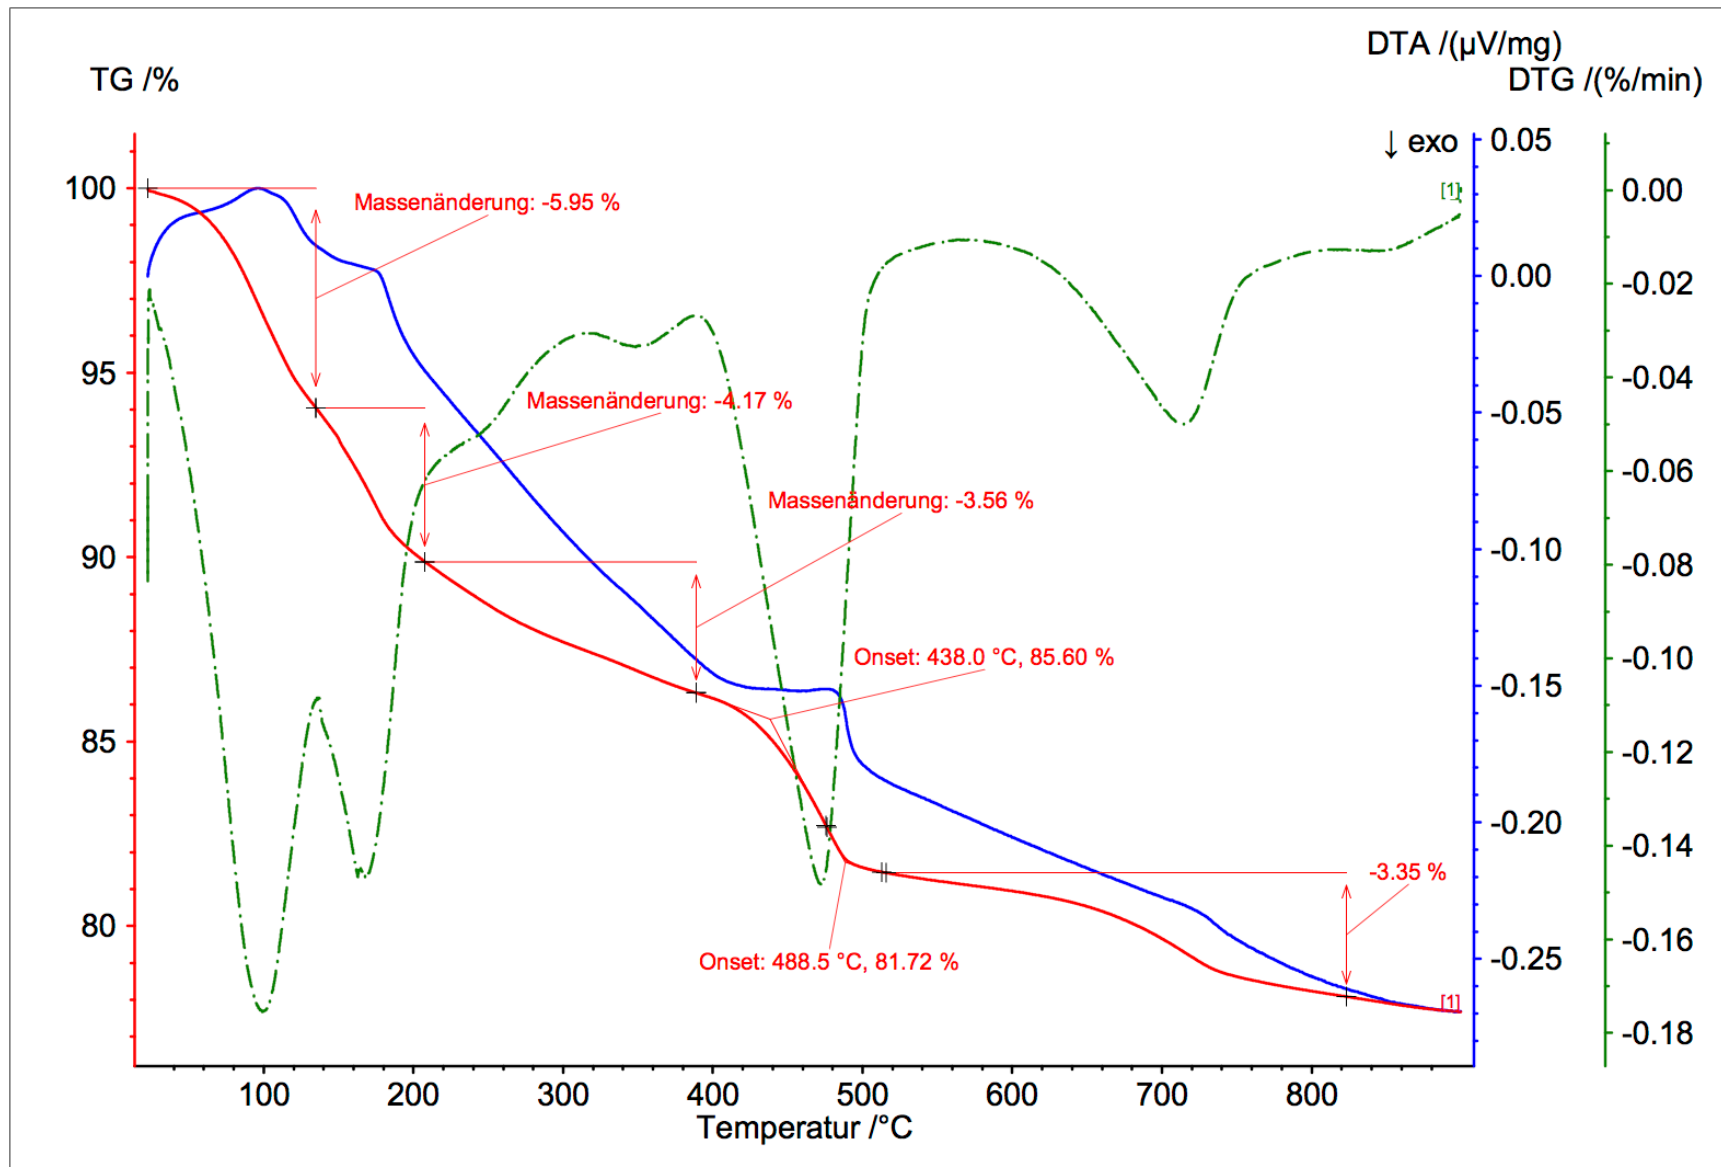

7	Evolved gas detection	EGD	Thermal conductivity cell	T.C.	T.C. vs temp
8	Dialotometry	TMA	Dialatometer	Vol.of Length	Vol or length vs temp
9	Electrical conductivity	EC	Electrometer or Bridget	Current or resistance	I or R vs temp
10	Emanation Thermal Analysis	ETA	ETA appts.	Radioactivity	E vs temp

1. **DTA** will provide the temperature necessary to establish a nearly zero temperature difference between the sample and the inert reference.
2. **DSC** measures the energy necessary to establish a nearly zero temperature difference between the sample and the inert reference
3. **TGA** will give mass change in milligram/microgram as a function of time or temperature subjected to heating.
4. **DTG** will provide the percentage and peak temperature of sample mass change rate with temperature and/or time.
5. In brief, the **DSC/DTA** measure the heat flow/temperature and the **TGA/DTG** measure the weight change of the sample subjected to heating.

Examples of the DTA analyses of some minerals and rocks

FIG. 10.11. DTA curves for: *A*—typical calcite (Faust, 1950); *B*—aragonite (Faust, 1950); *C*—natural calcite; *D*—sample giving curve *C*, calcined, hydrated and partially recarbonated.

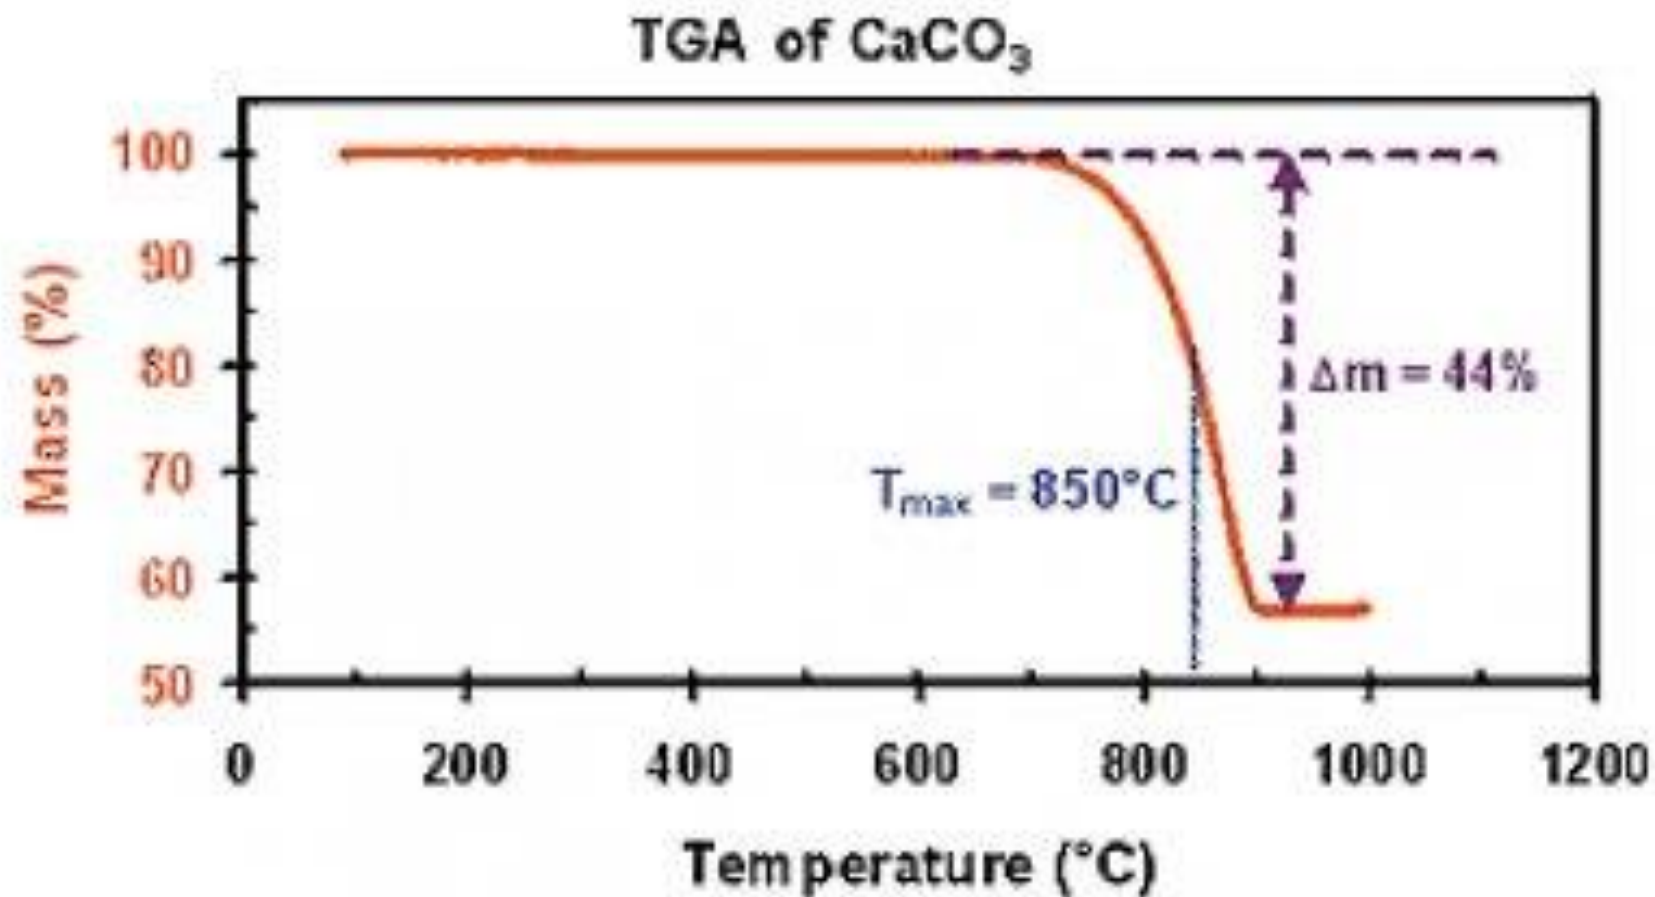

The decomposition of **Calcite** (Fig. A) into lime “**CaO**” starts around 850 and ends at 1020, but maximized at **1000 °C**

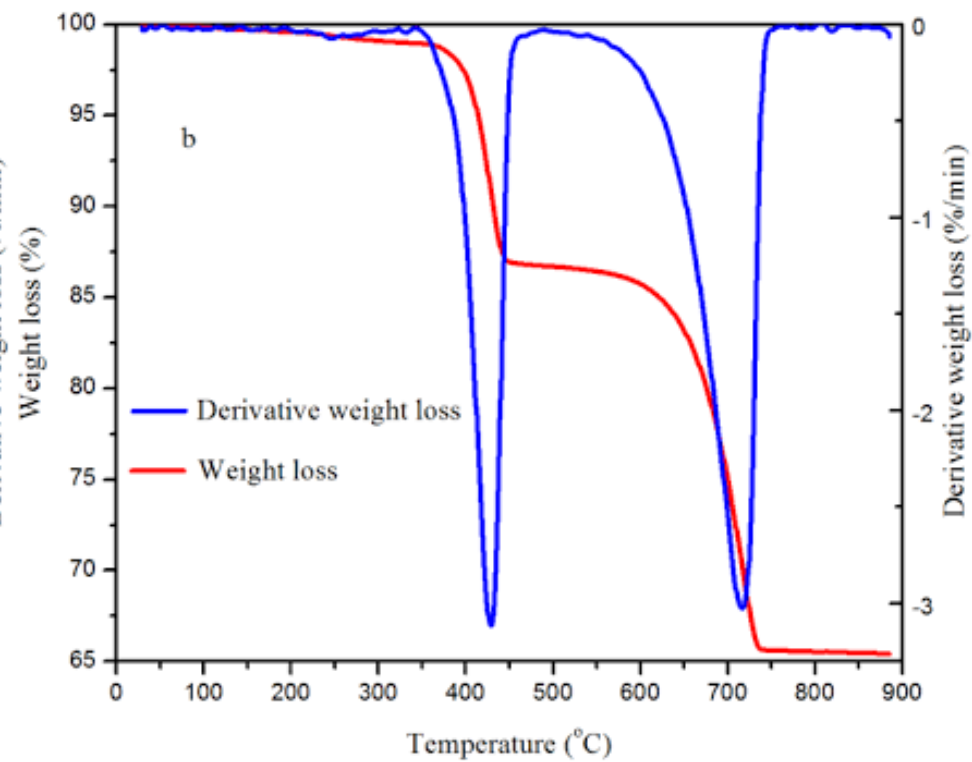

The decomposition of **Aragonite** (Fig. B) occurs at two steps:

1. The first is the **irreversible conversion of aragonite to calcite**. This begins around 460, ends at 520, but maximized at 500 °C.
2. The second step is the decomposition of **Calcite** into lime “**CaO**”. This begins around 800, ends at 960 and maximized around 930 °C

Thermal behavior of calcite

FIG. 10.14. DTA curves for different samples of dolomite.

The decomposition of **Dolomite** ($\text{Ca Mg}(\text{CO}_3)_2$) occurs on two steps:

1. The first is to break apart the dolomite structure into $\text{MgCO}_3 \cdot \text{CaCO}_3$ then the decomposition of the **Magnesite** part (MgCO_3) into periclase "**MgO**" and **CO₂**. This begins around 690, ends at 850 and maximized at 830 °C.
2. The second step is the decomposition of the **Calcite** (CaCO_3) part into lime "**CaO**" and **CO₂**. This begins around 850, ends at 1020 and maximized around 960 °C.
